Relational Database Design Methodology

Outline

Declaring integrity constraints

Triggers

Views

Static integrity constraints (1)

Restrict the possible states of the database

- Describe conditions that every instance of a database must satisfy
- Avoid erroneous insertions, updates, deletions
- Enforce data consistency
- Tell the DBMS information that is useful for data storing and retrieval (query optimization)

Types

- Domain constraints
- Non-null constraints
- ► Keys unique constraints
- Referential integrity
- General constraints at tuple level
- Assertions

Static integrity constraints (2)

Declaration

- At (table) creation(CREATE TABLE)
- After (table) creation (ALTER TABLE)

Validation

- At every DML statement
- At the end of the transaction

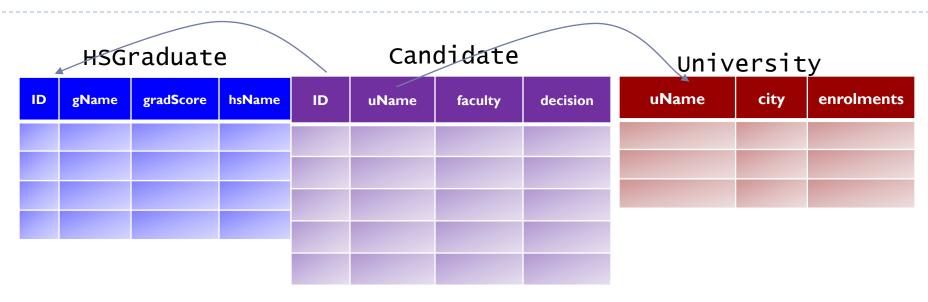

Integrity constraints over 1 attribute *Inline* declaration

```
CREATE TABLE table_name (
al type not null, -- does not allow null entries
a2 type unique, -- candidate key consisting of one attribute
a3 type primary key, -- primary key consisting of one attribute, implies {not null, unique}
a4 type references table_name2 (b1), --foreign key consisting of one attribute
a5 type check (condition) – the condition is a Boolean expression built with attribute a5: (a5<11 and
  a5>4), (a5 between 5 and 10), (a5 in (5,6,7,8,9,10))...
```

Integrity constraints over several attributes Out-of-line declaration

```
CREATE TABLE table_name (
al type,
a2 type,
a3 type,
a4 type,
primary key (a1,a2), -- primary key consisting of two (or more )attributes
unique(a2,a3), -- candidate key consisting of two (or more )attributes
check (condiție), -- a Boolean expression built over several attributes: ((a l +a3)/2>=5)
foreign key (a3,a4) references table_name2(b1,b2) — multi-valued foreign key
```

Referential integrity Definitions

- ▶ Referential integrity from R.A to S.B:
 - Every value in column A of table R must appear in column B of table S
 - A is called a foreign key
 - B must be declared as primary key or unique for table S
- There may exist multi-valued foreign keys

Referential integrity Validation

- Statements that may generate violations:
 - ▶ Insertions in R
 - Deletions in S
 - Updates of R.A or S.B
- Special actions that can be enforced:
 - At deletions in S:

ON DELETE RESTRICT (by default) | SET NULL | CASCADE

At updates on S.B:

ON UPDATE RESTRICT (by default) | SET NULL | CASCADE

Referential integrity egg or chicken?

```
CREATE TABLE chicken (clD INT PRIMARY KEY,
elD INT REFERENCES egg(elD));
CREATE TABLE egg(elD INT PRIMARY KEY,
clD INT REFERENCES chicken(clD));
```

Referential integrity egg or chicken?

```
CREATE TABLE chicken (cID INT PRIMARY KEY,
eID INT REFERENCES egg(eID));
CREATE TABLE egg(eID INT PRIMARY KEY,
cID INT REFERENCES chicken(cID));
```

CREATE TABLE chicken(cID INT PRIMARY KEY, eID INT); CREATE TABLE egg(eID INT PRIMARY KEY, cID INT);

ALTER TABLE chicken ADD CONSTRAINT chickenREFegg FOREIGN KEY (eID) REFERENCES egg(eID) DEFERRABLE INITIALLY DEFERRED; -- Oracle

ALTER TABLE egg ADD CONSTRAINT eggREFchicken FOREIGN KEY (cID) REFERENCES chicken(cID) DEFERRABLE INITIALLY DEFERRED; -- Oracle

INSERT INTO chicken VALUES(1, 2); INSERT INTO egg VALUES(2, 1); COMMIT;

How do you solve insertions if the constraints are validated at each statement?
What about table drops?

Asertions -defined in the SQL standard -

```
create assertion Key
check ((select count(distinct A) from T) =
          (select count(*) from T)));
```

Integrity constraints DBMS implementations

- Postgres, SQLite, Oracle, MySQL(innodb) implement and validate all constraints above
- No DBMS allows queries in the check constraint (deviation from the SQL standard)
- ▶ No DBMS implements assertions their functionality can be provided by triggers

...DEMO... (file constraints.sql)

Triggers Dynamic constraints

- Monitor all the changes in a database, check conditions and initiate actions
- Event-condition-action rules
 - Bring within the DBMS elements from the application logic
 - Enforce constraints that cannot be expressed otherwise
 - Are expressive
 - May implement repairing actions
 - The implementation may differ among DBMSs, the examples in the presentation are in accordance with the SQL standard

Triggers Implementation

```
Create Trigger name
Before After Instead Of event
[Referenced-variables]

[For Each Row] -- the action is executed for each row altered by the event (row vs. statement types)

[When (condition)] - a boolean expression – exactly as within the WHERE clause in SQL queries

action – in the SQL standard it's just a SQL statement, but in DBMSs implementing procedural extensions it may be a procedural block
```

- event:
 - ▶ INSERT ON table
 - DELETE ON table
 - ▶ UPDATE [OF a1,a2,...] ON table
- Referenced-variabiles (they are declared and then used in condition and action):
 - OLD TABLE AS var
 - NEW TABLE AS var
 - ▶ OLD ROW AS var only for DELETE, UPDATE
 - ▶ NEW ROW AS var —only for INSERT, UPDATE

Only for ROW triggers

Triggers Example

Referential integrity from R.A to S.B implementing cascade deletes

Create Trigger Cascade_Deletes
After Delete On S
Referencing Old Row As O
For Each Row
[no conditions]
Delete From R Where A = O.B

Create Trigger Cascade_Deletes
After Delete On S
Referencing Old Table As OT
[For Each Row]
[no condition]
Delete From R Where

A in (select B from OT)

Triggers Problems to consider

- Several triggers are activated simultaneously: which one is the first to be executed?
- ▶ The trigger action activates other triggers: chaining that can create cycles

Triggers Implementation

Postgres

- The closest to the standard
- implements row+statement -> {old,new}x{row,table} variables
- The syntax suffers some changes

SQLite

- Only row (no old/new table)
- Are executed for each row modification

MySQL

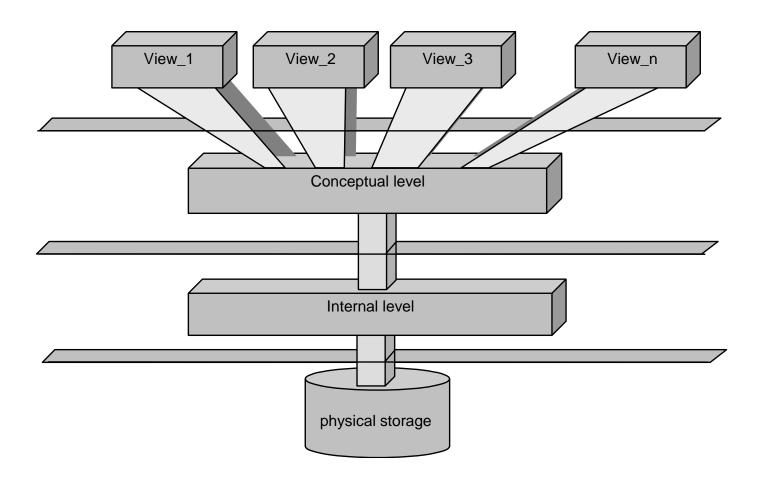

- Only row (no old/new table)
- Are executed for each row modification
- In earlier versions it allowed only one trigger per event per table

Oracle

- Implements the standard: row+statement, some syntax changes
- Instead-of triggers are allowed only for views
- Allows the use of procedural blocks
- Introduced the "FOLLOWS" clause in 1 Ig
- Introduced restrictions to avoid cycling
- Studied more at the lab in the second semester

...DEMO... (file triggers.sql)

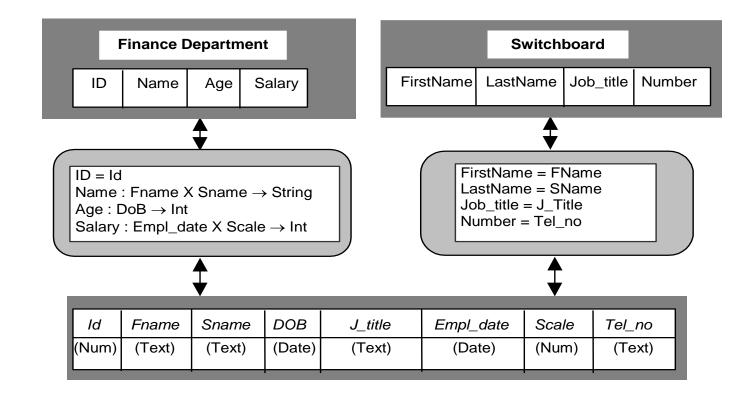

Views

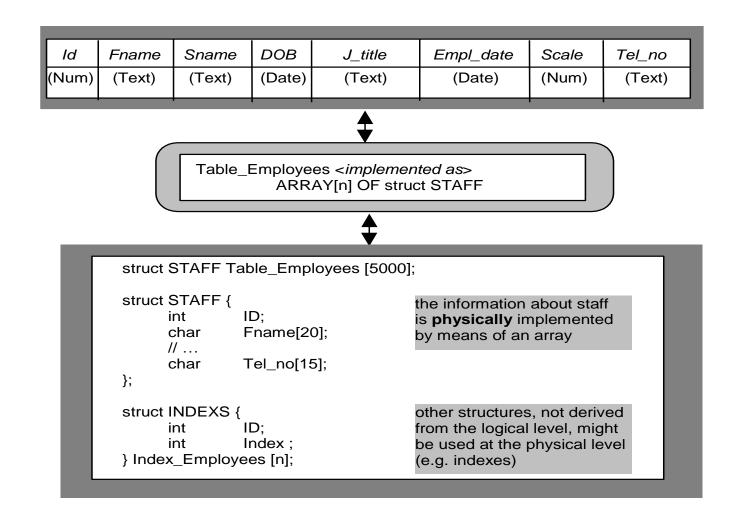

Codd's 12 rules

- 1. Information Rule
- 2. Guaranteed Access Rule
- 3. Comprehensive Data Sub-language Rule
- 4. View Update Rule
- 5. High Level Insert, Update and Delete
- Physical Data Independence
- Logical Data Independence
- 8. Integrity Independence
- 9. Non Subversion Rule
- 10. Systematic Treatment of Null Values
- 11. Database Description Rule
- 12. Distribution Independence

External level/conceptual level mapping

Conceptual level/internal level mapping

Motivation

▶ Controlled access to the data:

- hide data from specific users
- restrict DML statements
- Reduce the complexity of writing queries

Real applications tend to use many views

Definition and use

- A view is actually a stored query formulated over tables or other views
- Its schema is generated based on the schema of the query result
- Conceptually, a view is queried just like a table
- In reality, a query over a view is rewritten by replacing the name of the view with the query defining the view; query optimization takes place, as implemented by the DBMS
- Syntax

Create View view_name [(a1,a2,...)] As <select_statement>

Modifying views

- Although the main operation/statement executed on a view is querying it, they may allow DML operations
- Modification commands on views must be rewritten as modification commands over base tables
 - Usually is simple
 - Sometimes several ways exist
- Example I
 - Arr R(A,B),V(A)=R[A];
 - INSERT INTO V VALUES(3);
- Example 2
 - ightharpoonup R(N), V(A) = avg(N),
 - ▶ UPDATEV SET A=7;

Modifying views Approaches

- I. The view owner must rewrite all DML statements launched on the view as DML statements on the tables using the INSTEAD OF trigger
 - Covers all the cases
 - Guarantees data consistency
- 2. The SQL standard defines the existence of (inherently) **updatable views**:
 - The view must be created based on a single table T
 - The attributes in T that are not used in the view may have NULL entries or DEFAULT values
 - There is no aggregation used: no GROUP BY, no DISTINCT keyword

Materialized views

Create Materialized View V [a1,a2,...] As <select_statement>

- A new table V is created with schema defined by the select statement; the query is also stored
- The tuples result of the query are inserted into V
- Any query on V is executed directly on table V
- Advantages:
 - Specific to regular views + increased query execution speed
- Ddisadvantages:
 - Any DMLs on the base tables require modifications on V
 - Any DMLs on V still must be translated into DMLs on base tables

How decide if materialize?

- Data size
- Query complexity
- The number of queries on the view
- The number of modifications on the base tables and the possibility of incrementally updating the view
- Trade-off the time for query processing over the time for propagating updates on the view when DML commands occur on the base tables

...DEMO...
(file views.sql)
